

VERITRUST

IMPLEMENTATION HANDBOOK | 11 AUGUST 2026

# Deepfake Detection Architecture Blueprint

A complete, evidence-first implementation plan  
for models, media safety, training, calibration,  
deployment, scaling, observability and release.

- Two-task model strategy: facial manipulation and fully synthetic imagery
- Hugging Face candidate portfolio and model registry worksheet
- Interactive table of contents, links, fields and completion checklist
- Repository-grounded implementation sequence and acceptance tests

Status: implementation-ready design; model candidates remain benchmark-gated

Scope: image detection only; audio/video/C2PA are intentionally deferred

# How to use this handbook

## This is a build specification, not a performance claim

No probabilistic detector can be guaranteed 100% correct. Every model named here is a candidate until VeriTrust validates its exact revision on a frozen, legally usable, production-representative benchmark. A failed, unsupported, low-quality or out-of-distribution result must never be converted into safe evidence.

The document is interactive. Use the clickable table of contents and PDF outline to navigate. External references are clickable. The final operator worksheet contains fillable fields, and the release checklist contains interactive checkboxes.

## Decision that must be made first

VeriTrust currently uses the words deepfake, synthetic media and fake image as if they were one task. They are not. The implementation must maintain two separately benchmarked tracks:

| Track                     | Question answered                                                      | Input                                    | Primary evidence        |
|---------------------------|------------------------------------------------------------------------|------------------------------------------|-------------------------|
| A - Facial manipulation   | Was a real face or identity locally manipulated, swapped or reenacted? | One or more aligned face child artifacts | FACE_MANIPULATION_SCORE |
| B - Fully synthetic image | Was the complete image generated by an AI image generator?             | Deterministically normalized full frame  | SYNTHETIC_IMAGE_SCORE   |

The existing Pixel and Prism names may remain product aliases, but each alias must resolve through the Model Registry to one exact task, revision, preprocessing pipeline, label map, calibration package and benchmark version.

## Recommended reading order

- Executives/product: Sections 1, 3, 5, 16 and 20.
- Backend engineers: Sections 4, 7-13 and 16-18.
- ML engineers: Sections 5-6 and 14-15.
- Security/operations: Sections 7, 17-20.

# 1. Executive implementation decision

The existing application has credible foundations: protected uploads, basic byte and MIME checks, hashing, private object storage, asynchronous Gateway jobs, retention handling, rate limits and some model metadata. It is not yet the high-assurance deepfake system described in the VeriTrust Four Core Detection Architecture Blueprint.

## Release blockers found in the repository

| Priority | Finding                                                               | Required correction                                                                   |
|----------|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| P0       | Unknown provider labels are guessed from text or LABEL_1-like values. | Exact per-revision output label map; reject everything else.                          |
| P0       | Registry metadata is selected after provider inference.               | Resolve immutable model version before preprocessing or inference.                    |
| P0       | A failed selected model silently switches to the other model.         | Emit FAILED for that model; run a second detector only as independent evidence.       |
| P0       | Compressed bytes are bounded, decoded pixels and frames are not.      | Header limits plus bounded decode in an isolated media worker.                        |
| P0       | Raw score is used as probability, confidence, risk and verdict.       | Keep raw score, calibrated probability and decision confidence separate.              |
| P1       | Face crop differs between web, developer API and Gateway.             | One versioned server-side preprocessing pipeline.                                     |
| P1       | No quality/OOD/abstention pipeline exists.                            | Quality evidence and first-class UNCERTAIN/UNSUPPORTED/FAILED states.                 |
| P1       | No deepfake behavioral, benchmark or robustness tests exist.          | Provider fixtures, media security corpus, golden preprocessing and benchmark harness. |

## Non-negotiable scientific rules

- A specialist model produces typed evidence. It never produces ALLOW or BLOCK.
- LIKELY\_REAL means evidence leans real within a qualified benchmark scope. It never certifies authenticity.
- Missing evidence, provider failure or an unsupported input is not negative evidence.
- No threshold is promoted until held-out calibration and release-delta tests pass.
- Model disagreement is stored, displayed and used to reduce sufficiency.
- Same artifact + preprocessing version + model revision must be reproducible.

# 2. Scope, terminology and trust boundary

## In scope

- JPG, PNG and WebP still images after explicit capability validation.
- Full-frame AI-generated-image detection.
- Face discovery, alignment and image-level face manipulation detection.
- Quality measurement, limited OOD handling, calibration, disagreement and abstention.
- Hugging Face Hub-hosted model artifacts, dedicated endpoints or self-hosted inference.
- Direct web API, developer API and Gateway integration through one canonical engine.

## Explicitly deferred

- Video temporal models, audio deepfake detection, C2PA/provenance and source attribution.
- Generator-family attribution, localization masks as forensic proof and biometric identity recognition.

- Automated punitive action based only on a deepfake model.

## Vocabulary

| Term                   | Definition                                                                                               |
|------------------------|----------------------------------------------------------------------------------------------------------|
| Raw score              | A value emitted by a declared model head. It is not automatically a probability.                         |
| Calibrated probability | A versioned transformation evaluated on held-out data for a declared scope.                              |
| Quality                | Measurable image conditions that affect model validity or evidence sufficiency.                          |
| OOD                    | Input outside the qualified content/generator/transformation regimes. Heuristics alone cannot prove OOD. |
| Evidence sufficiency   | Whether required evidence classes and quality are present for a scoped verdict.                          |
| Decision confidence    | Gateway-level confidence in a policy decision; never copied from one model score.                        |

## 3. Repository-grounded current architecture

The direct web route and developer API call the same detection service. The Gateway downloads private media in a worker and then calls an adapter that reaches the same detection service. This reuse is valuable, but the shared core currently normalizes unknown model labels heuristically and treats the second detector as a fallback.

## Relevant files

| Area                   | File                             | Current responsibility                                           |
|------------------------|----------------------------------|------------------------------------------------------------------|
| Model aliases/provider | lib/veritrust-api.js             | Pixel/Prism names, Hugging Face requests and multipart parser.   |
| Detection core         | lib/detection-service.js         | Heuristic label normalization, model fallback and legacy result. |
| Input validation       | lib/validators.js                | 4 MB, declared MIME and basic magic-byte checks.                 |
| Web route              | lib/routes/detection/deepfake.js | Authenticated saved scan and SHA-256.                            |
| Developer API          | lib/routes/v1/deepfake.js        | API-key scan and optional external crop service.                 |
| Gateway adapter        | lib/models/deepfake-image.js     | Maps fake score to safe/suspicious/manipulated.                  |
| Media worker           | worker/handlers/media.js         | Downloads, validates, hashes, runs adapter and finalizes.        |
| Registry metadata      | lib/gateway/persistence.js       | Selects gateway_model_versions while recording evidence.         |
| UI                     | assets/js/pages/detection.js     | Crop, submit and probability-style result rendering.             |

## What should be preserved

- Existing authentication, API-key scope, rate limit and entitlement boundaries.
- Private object storage, retention jobs, queue leases, idempotency and cancellation foundations.
- Provider request size/time limits and response redaction.
- The public model-performance page's honest statement that no benchmark is currently published.

## 4. Target deepfake architecture

## End-to-end invariant

### Resolve before execution

The registry is read before preprocessing. The resolved immutable ModelVersion object drives the exact task, revision, input size, crop policy, normalization, label map, calibration and benchmark metadata. The same object is persisted with the model run.

## Two-track model topology

Track A and Track B may both run for a face image, but their observations remain distinct. Their values are not averaged. A future Gateway correlation rule can reason over relationships and disagreement.

## 5. Hugging Face model portfolio and selection

### Candidate does not mean approved

The following models are a benchmark shortlist as of 11 August 2026. Production use requires license review, supply-chain scanning, exact commit pinning, local reproduction, task validation, calibration and VeriTrust benchmark approval. The hidden Pixel/Prism IDs cannot be recovered from the repository because they are intentionally server configuration.

### Recommended portfolio

| Role / proposed key                                     | Candidate                                          | Why shortlist it                                                                                         | Deployment status                                                                       |

| Synthetic latency/shadow<br>synthetic_commfors_224      | OwensLab/commfors-model-224                        | Official 21.7M-parameter lower-input companion for latency/cost comparison.                              | Shadow candidate; promote only if slice gates pass.                                     |
| Independent forensic secondary<br>forensic_frequency_v1 | Train and upload a private VeriTrust model         | SRM/DCT/noise-residual branch provides a different feature family from semantic ViT/CLIP models.         | Train only if it materially improves selective risk and disagreement handling.          |
| Quality/OOD head<br>media_quality_ood_v1                | Deterministic metrics + trained embedding OOD head | No generic off-the-shelf OOD model can be trusted for VeriTrust's production distribution.               | Build after collecting qualified train/calibration/OOD splits.                          |

## How Pixel and Prism should work

Keep Pixel and Prism only as customer-facing aliases. Do not store their display names as contract keys. A possible mapping is shown below; the final mapping depends on the exact models already configured in deployment.

| Display alias   | Registry deployment    | Allowed task            | Behavior                                       |
|-----------------|------------------------|-------------------------|------------------------------------------------|
| VeriTrust Pixel | synthetic_commmor_384@ | fully_synthetic_image   | Full-frame evidence only.                      |
| VeriTrust Prism | face_clip_l14_v1@      | face_manipulation_image | Requires one or more qualified face artifacts. |

If the currently deployed Pixel/Prism models have different scientific tasks, preserve their real task declarations and change the UI rather than forcing the aliases into this proposed mapping.

## Model parameter cards

### A. OpenCV YuNet face detector

| Parameter            | Starting contract                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------|
| Purpose              | Find face boxes and five landmarks; create child artifacts. It does not classify authenticity.                |
| Artifact             | opencv/opencv_zoo/models/face_detection_yunet/face_detection_yunet_2026may.onnx or a vetted 2023mar revision. |
| Format/runtime       | ONNX; OpenCV DNN or ONNX Runtime CPU worker.                                                                  |
| Input                | Deterministically oriented RGB image; dynamic or registry-declared detector input size.                       |
| Detection threshold  | Start at 0.8 for evaluation; select from recall/precision testing, not preference.                            |
| NMS threshold        | Start at 0.3; freeze in preprocessing_version.                                                                |
| Top faces            | Maximum 10; each qualified face becomes a child artifact.                                                     |
| Minimum face         | Start at 96 x 96 source pixels; below threshold becomes LOW_FACE_RESOLUTION.                                  |
| License/supply chain | Pin commit and ONNX SHA-256; archive license and upstream source.                                             |

### B. Face manipulation primary - CLIP ViT-L/14 candidate

| Parameter     | Starting contract                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| Hub candidate | yermady/deepfake-detection, pinned to a verified commit after weight scanning/conversion.                                 |
| Backbone      | openai/clip-vit-large-patch14; 224 x 224 CLIP image input unless the pinned project declares otherwise.                   |
| Task          | Binary facial manipulation evidence on aligned/cropped faces, not generic AI-image detection.                             |
| Preprocessing | Use exact project/pinned processor. Freeze resize, crop, RGB conversion, mean/std and interpolation.                      |
| Output map    | Must be extracted from exact code/checkpoint and proven by golden fixtures. No generic LABEL_0/LABEL_1 assumption.        |
| Runtime       | Dedicated GPU container; do not route through generic HF serverless inference because the model is not provider-deployed. |
| Weight format | Prefer Safetensors. Treat pickle checkpoints and TorchScript as untrusted artifacts; scan and convert in isolation.       |
| Calibration   | Separate temperature/isotonic transform qualified on untouched face-manipulation calibration data.                        |

## C. Synthetic-image primary - Community Forensics 384

| Parameter        | Starting contract                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------|
| Hub candidate    | OwensLab/commfor-model-384, exact commit and Safetensors SHA-256 pinned.                             |
| Architecture     | ViT-small family; approximately 21.8M parameters; 384-pixel model track.                             |
| Task             | Fully AI-generated image vs real image. Do not use as proof of local face manipulation.              |
| Input            | Full frame; exact official preprocessor/config at pinned revision is authoritative.                  |
| Labels           | Freeze exact head semantics in registry and test with reference fixtures before any production call. |
| Runtime          | Dedicated CPU/GPU benchmark first; GPU worker recommended for predictable tail latency.              |
| Training lineage | Community Forensics model family; candidate card lists Safetensors and MIT model license.            |
| Calibration      | Per-version calibration on VeriTrust production-like data; do not reuse model-card thresholds.       |

## D. Independent forensic secondary

Do not choose a second ViT merely because it has a different repository name. Independence should be measured by error correlation. If a secondary detector is needed, train a compact branch over SRM/high-pass residuals, DCT statistics or multi-scale noise residuals, then prove it catches different failures. Upload the resulting Safetensors/ONNX artifact to a private Hugging Face repository and register its exact commit.

# 6. Authoritative Model Registry

## Required registry fields

| Field                 | Requirement                                                                    |
|-----------------------|--------------------------------------------------------------------------------|
| model_key             | Stable internal key; never a display name.                                     |
| task                  | face_manipulation_image, fully_synthetic_image, face_detection or quality_ood. |
| provider              | hf_dedicated, self_hosted_onnx, self_hosted_torch or approved alternative.     |
| repository + revision | Exact Hugging Face repository and immutable commit SHA; never main.            |
| artifact_sha256       | Digest of every downloaded weight/config/processor artifact.                   |
| input_contract        | MIME, dimensions, frames, colorspace, crop policy and processor details.       |
| output_label_map      | Exact raw provider label/index to VeriTrust observation semantics.             |
| preprocessing_version | Immutable code/config version and deterministic output contract.               |
| calibration_version   | Transform, fitting manifest and validated thresholds; null until qualified.    |
| benchmark_version     | Frozen evaluation manifest and report checksum; null until qualified.          |
| deployment_status     | disabled, shadow, canary, production or rolled_back.                           |
| rollout               | Deterministic cohort, start/end, target share and rollback predecessor.        |
| license + approval    | License text checksum, commercial-use review and approver.                     |

## Registry resolution flow

Request -> capability check -> task routing -> registry resolution -> rollout cohort -> exact preprocessing -> exact inference adapter -> evidence persistence. If any registry field needed for execution is missing, the result is UNSUPPORTED or FAILED before provider inference.

Recommended implementation: a shared model\_versions table plus immutable calibration\_versions and benchmark\_versions. If the deployed gateway\_model\_versions table is retained, create a compatibility view or migration; do not maintain two independent registries.

## 7. Media ingestion and bounded validation

### Initial capability defaults

| Control             | Synchronous path                                | Asynchronous object-storage path | Failure state              |
|---------------------|-------------------------------------------------|----------------------------------|----------------------------|
| Request bytes       | 4 MiB maximum including multipart safety margin | 20 MiB initial maximum           | IMAGE_TOO_LARGE            |
| Formats             | JPEG, PNG, static WebP                          | JPEG, PNG, static WebP           | UNSUPPORTED_MEDIA_TYPE     |
| Minimum dimensions  | 64 x 64 full frame                              | 64 x 64 full frame               | RESOLUTION_TOO_LOW         |
| Maximum side        | 8,192 pixels                                    | 8,192 pixels                     | DIMENSION_LIMIT_EXCEEDED   |
| Maximum pixels      | 40 megapixels                                   | 40 megapixels                    | PIXEL_LIMIT_EXCEEDED       |
| Frames/pages        | Exactly 1                                       | Exactly 1                        | ANIMATED_MEDIA_UNSUPPORTED |
| Channels            | 1-4 decoded; normalized to RGB                  | 1-4 decoded; normalized to RGB   | CHANNEL_LIMIT_EXCEEDED     |
| Decoded budget      | 160 MiB maximum                                 | 160 MiB maximum                  | DECODE_BUDGET_EXCEEDED     |
| Metadata budget     | 256 KiB                                         | 256 KiB                          | METADATA_LIMIT_EXCEEDED    |
| Validation deadline | 3 seconds                                       | 3 seconds                        | MEDIA_VALIDATION_TIMEOUT   |

These are safe starting defaults, not eternal constants. Publish them through `/api/system/capabilities` and change them only through versioned configuration plus security/load regression.

### Validation sequence

- Authenticate and authorize before accepting or registering content.
- Assign `artifact_id`; stream SHA-256 while receiving or downloading bytes.
- Validate declared MIME, extension when relevant and independent file signature.
- Read bounded metadata with safety features enabled; reject animation/multipage content.
- Enforce width, height, pixel, channel and metadata budgets before decode.
- Perform one bounded decode in an isolated media worker; capture warnings as evidence.
- Never log raw bytes, EXIF, faces, original filename or signed object URLs.
- Store bytes privately under generated paths and governed retention.

## 8. Deterministic preprocessing specification

### Shared normalization

| Step        | Versioned behavior                                                                            |
|-------------|-----------------------------------------------------------------------------------------------|
| Orientation | Apply EXIF orientation once; record original orientation and remove it from derived output.   |
| Colorspace  | Convert to sRGB using a pinned image library/runtime version.                                 |
| Alpha       | Flatten against a declared background color; do not silently discard transparency.            |
| Bit depth   | Convert through a declared path to 8-bit RGB for models that require it.                      |
| Metadata    | Strip nonessential metadata from derived model input; retain only governed evidence metadata. |
| Resize      | Model-specific size, aspect policy, interpolation and crop; all registry-controlled.          |
| Output hash | SHA-256 of canonical derived bytes plus a preprocessing manifest checksum.                    |

### Track A - face manipulation

- Run the pinned face detector on the normalized full frame.
- Create a parent-child artifact edge for every qualified face, up to the configured cap.
- Use five landmarks for alignment when the model contract requires it.
- Apply a fixed margin (start 0.15) and deterministic padding/resize policy.
- Never silently choose face index zero as the only evidence when multiple faces exist.
- If there is no face, emit NO\_QUALIFIED\_FACE; do not fall back to a generic face model on the full image.

### Track B - fully synthetic image

- Use the whole normalized image; face detection is not required.
- Follow the pinned official processor exactly, including resize/crop and normalization.
- Record transformations that may remove forensic traces, including screenshot/re-encode and aggressive resize.

### Golden reproducibility test

Maintain a small legal fixture set. For every preprocessing version, CI verifies exact output dimensions, metadata manifest and SHA-256 on the supported production runtime. A hash change requires a new preprocessing version and benchmark delta.

## 9. Quality, OOD and evidence sufficiency

### Quality evidence families

| Family         | Measurements                                                                   | Example reason codes                  |
|----------------|--------------------------------------------------------------------------------|---------------------------------------|
| Decode         | decoder warnings, truncated data, color conversion, frame count                | DECODE_WARNING, TRUNCATED_IMAGE       |
| Resolution     | full-frame and face dimensions, resize ratio                                   | LOW_RESOLUTION, LOW_FACE_RESOLUTION   |
| Sharpness      | variance of Laplacian or qualified equivalent by content slice                 | EXCESSIVE_BLUR                        |
| Compression    | format, estimated JPEG quality, blockiness and repeated transcoding indicators | HEAVY_COMPRESSION, REENCODED_MEDIA    |
| Exposure       | luminance distribution, clipped dark/light fraction                            | UNDEREXPOSED, OVEREXPOSED             |
| Face geometry  | landmark confidence, pose, occlusion, face-area ratio                          | FACE_POSE_OOD, FACE_OCCLUDED          |
| Content regime | embedding distance/energy against qualified in-distribution reference          | CONTENT_OOD, GENERATOR_REGIME_UNKNOWN |

### Important OOD limitation

#### Do not market a heuristic as OOD detection

Blur, low resolution and compression are quality signals. A real OOD system requires a declared reference distribution and held-out OOD evaluation. Start with explicit quality abstention. Add an embedding-distance, density or energy-based OOD head only after it improves selective risk on frozen OOD datasets.

### Sufficiency rule examples

- LIKELY\_REAL requires validated media, acceptable quality, in-scope task, qualified calibration and no strong disagreement.
- LIKELY\_SYNTHETIC requires threshold-qualified model evidence and sufficient quality; the Gateway still owns action.
- Low quality, OOD, missing calibration or conflicting models produces UNCERTAIN.
- Unsupported task or absence of a qualified face for Track A produces UNSUPPORTED.
- Decode/provider/runtime failure produces FAILED with null semantic score.

## 10. Inference adapter contract

### Adapter input

artifact\_id, derived\_artifact\_id, resolved ModelVersion, preprocessing manifest/hash, deadline, cancellation signal, tenant-safe trace context and request idempotency key.

### Adapter output

provider status, raw provider schema version, exact labels/scores, normalized observation, latency, attempt number, error class and redacted response reference. The adapter does not calculate final risk or action.

### Hugging Face integration rules

- Use repository@commit, not repository@main.
- Validate config, processor and weight SHA-256 at image build or controlled model acquisition.
- Prefer Safetensors/ONNX. Treat pickle-based files as untrusted and convert only inside an isolated build process.

- Use a dedicated Hugging Face endpoint or self-hosted container for models not deployed by Inference Providers.
- Schema-validate every label and finite score. Reject unknown labels, missing expected classes and duplicates.
- Retry only classified transient errors such as 429/selected 5xx, with bounded exponential backoff and jitter.
- Use provider bulkheads, a circuit breaker and per-model concurrency budgets.
- Never retry unsupported output, invalid input or deterministic preprocessing failures.

## Error taxonomy

| Class       | Examples                                                    | Evidence behavior                                       |
|-------------|-------------------------------------------------------------|---------------------------------------------------------|
| UNSUPPORTED | task mismatch, unknown label, animation, no qualified face  | UNSUPPORTED; null semantic probability                  |
| FAILED      | timeout, provider outage, invalid JSON, weight load failure | FAILED; preserve attempt and provider version           |
| UNCERTAIN   | low quality, OOD, disagreement, missing calibration         | Completed evidence with abstention                      |
| RETRYABLE   | 429, transient 502/503, lease-safe worker interruption      | Retry under job budget; never return safe while pending |

# 11. Normalization, calibration and thresholds

## Data fields that must remain separate

| Field                  | Meaning                                                               | May be null?                           |
|------------------------|-----------------------------------------------------------------------|----------------------------------------|
| raw_score              | Exact declared model output after label mapping.                      | No for successful model output         |
| normalized_score       | Deterministic score orientation, for example higher = more synthetic. | Yes                                    |
| calibrated_probability | Versioned held-out calibration output for a qualified scope.          | Yes until validated                    |
| quality_score          | Versioned aggregation of declared quality measurements.               | Yes                                    |
| evidence_sufficiency   | Whether required evidence/quality classes are available.              | No                                     |
| decision_confidence    | Gateway policy/correlation confidence.                                | Always absent from specialist evidence |

## Calibration workflow

- Hold out calibration data by source identity, video, generator family and capture pipeline.
- Compare temperature scaling, Platt/logistic scaling and isotonic regression.
- Select using Brier score, expected calibration error and reliability plots, not accuracy alone.
- Report bootstrap confidence intervals and slice calibration.
- Freeze transform coefficients, fitting manifest/hash and software version.
- Use business costs to choose review/synthetic evidence thresholds; never use arbitrary 0.45/0.75 values.

## Before calibration

The API may return `raw_score` and `normalized_score`, but `calibrated_probability` must be null and the evidence verdict should normally remain `UNCERTAIN` unless a non-probabilistic benchmark-qualified rule explicitly supports another evidence state.

## 12. Disagreement and abstention state machine

### Disagreement policy

- Run a second detector only for policy-selected high-impact requests, shadow evaluation or qualified ensemble routing.
- Persist one evidence object per model. Never overwrite the primary or average scores into false certainty.
- Measure model error correlation before calling a detector independent.
- Strong contradictory calibrated evidence produces UNCERTAIN and mandatory review when the media is material.

### Evidence verdict definitions

| Verdict          | Operational meaning                                                                             |
|------------------|-------------------------------------------------------------------------------------------------|
| LIKELY_REAL      | Qualified evidence leans real within the declared task/benchmark scope; not authenticity proof. |
| LIKELY_SYNTHETIC | Qualified evidence leans synthetic/manipulated within the declared scope.                       |
| UNCERTAIN        | Weak, low-quality, OOD, uncalibrated or conflicting evidence.                                   |
| UNSUPPORTED      | Input/model/task is outside the declared capability contract.                                   |
| FAILED           | Processing/provider failed; no semantic verdict is inferred.                                    |

## 13. Canonical data and API contracts

### Artifact example

```
{ "artifact_id": "uuid", "parent_artifact_id": null, "type": "image", "source": "web", "sha256": "hex",
  "mime_type": "image/jpeg", "byte_size": 1834210, "retention_class": "temporary_private",
  "schema_version": "artifact.v1" }
```

### Deepfake Evidence example

```
{ "evidence_id": "uuid", "artifact_id": "uuid", "evidence_type": "synthetic_image_model", "source": {
  "adapter": "deepfake_evidence_adapter.v1", "provider": "self_hosted_torch", "model_key":
  "synthetic_commf0r_384", "revision": "40-char-commit-sha" }, "observation": { "verdict": "UNCERTAIN",
  "raw_score": 0.82, "calibrated_probability": null }, "quality": { "status": "PASS", "score": 0.91,
  "reasons": [] }, "reason_codes": ["CALIBRATION_NOT_QUALIFIED"], "preprocessing_version":
  "fullframe.v1", "calibration_version": null, "benchmark_version": null, "schema_version":
  "evidence.deepfake.v1" }
```

## Recommended API behavior

| Endpoint                                         | Behavior                                                                        |
|--------------------------------------------------|---------------------------------------------------------------------------------|
| POST /api/v2/deepfake/investigations             | Register artifact/requested tasks; return 202 with durable job for heavy media. |
| GET /api/v2/deepfake/investigations/{id}         | Return status, artifacts, model attempts, evidence and progress.                |
| POST /api/v2/deepfake/investigations/{id}/cancel | Idempotent cancellation request.                                                |
| GET /api/system/capabilities                     | Authoritative MIME, byte, pixel, task, model and degraded-state truth.          |
| GET /api/models                                  | Admin/operator registry view; public view exposes approved model cards only.    |

Existing /api/deepfake and /api/v1/deepfake should become compatibility wrappers over the canonical engine. They may project legacy fields during a deprecation window, but internal truth must be the versioned Artifact/Evidence model.

## 14. Training and fine-tuning plan

### Training is conditional, benchmarking is mandatory

Start by reproducing and benchmarking the shortlisted models. Train or fine-tune only if no candidate meets the declared slice, robustness, calibration, latency and license gates. This avoids spending GPU time before the task and data contract are correct.

## Dataset strategy

| Dataset/source                             | Use                                                | Restriction/action                                                                                                  |
|--------------------------------------------|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| VeriTrust consented production-like corpus | Primary calibration, robustness and final holdout  | Required for commercial relevance; consent, provenance, retention and no train/test leakage.                        |
| Community Forensics / Small                | Synthetic-image research training and reproduction | Dataset card states research use and per-generator licenses; legal review required.                                 |
| Community Forensics Eval                   | Synthetic-image research comparison                | Non-commercial research/education license; not a commercial production qualification set.                           |
| FaceForensics++                            | Face manipulation research training/benchmark      | Terms restrict database to non-commercial research/education; do not use for commercial weights without permission. |
| Celeb-DF v2                                | Cross-dataset face manipulation evaluation         | Review dataset terms, identity/privacy and redistribution before use.                                               |
| DFDC                                       | Research cross-dataset evaluation                  | Subject to competition/data terms; consented paid actors, but commercial rights still require review.               |
| DF40                                       | Diverse research evaluation                        | CC BY-NC 4.0; research-only for commercial product development unless separately licensed.                          |

## Leakage-safe split rules

- Group face data by source identity and original video; derivatives never cross splits.
- Group generated images by generator family/checkpoint and source real image.
- Maintain generator-held-out, manipulation-held-out and transformation-held-out test sets.
- Keep calibration data completely separate from training and final test.
- Hash/near-duplicate scan every split with perceptual and embedding similarity.
- Freeze a final production holdout that model developers cannot inspect sample-by-sample.

## Training recipe A - fully synthetic image detector

| Parameter       | Recommended starting search space                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------|
| Backbone        | Reproduce OwensLab commfor-model-384 first; alternate ViT-S/16 384 only with pinned initialization.                        |
| Input           | 384 x 384 RGB; exact resize/crop and normalization recorded.                                                               |
| Objective       | Binary cross entropy/logit or 2-class cross entropy; compare generator-balanced sampling.                                  |
| Optimizer       | AdamW.                                                                                                                     |
| Learning rates  | Head 1e-4 to 5e-4; backbone 1e-6 to 5e-5. Select via validation, not one fixed value.                                      |
| Weight decay    | 0.01 to 0.1.                                                                                                               |
| Effective batch | 64-256 using gradient accumulation; log actual per-device batch.                                                           |
| Epochs          | 10-30 maximum with early stopping on generator-macro AP and selective risk.                                                |
| Schedule        | 5% warmup then cosine decay.                                                                                               |
| Precision       | BF16 where validated; FP32 metric accumulation.                                                                            |
| Augmentation    | JPEG/transcode, resize/crop, screenshot, blur/noise, overlays and platform transformations; do not create label artifacts. |
| Seeds           | At least 3; report mean and confidence interval.                                                                           |
| Checkpoint      | Best macro AP subject to FPR, calibration and slice floors; not lowest training loss.                                      |

## Training recipe B - face manipulation detector

| Parameter       | Recommended starting search space                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------|
| Backbone        | Pinned openai/clip-vit-large-patch14 visual encoder or reproduced yermamy method.                          |
| Input           | 224 x 224 aligned face unless pinned method declares otherwise.                                            |
| Adaptation      | Start with frozen backbone + linear/LN tuning; add PEFT only if cross-dataset validation improves.         |
| Learning rate   | 5e-5 to 1e-4 for head/LN parameters; lower for any unfrozen backbone blocks.                               |
| Effective batch | 32-128, balanced by real/fake and manipulation family.                                                     |
| Epochs          | 5-15 with cross-dataset early stopping; short PEFT schedules may be sufficient.                            |
| Loss            | Cross entropy; compare focal loss only when imbalance remains after sampling.                              |
| Face sampling   | Cap frames/faces per source video so long videos do not dominate.                                          |
| Augmentation    | Compression, blur, color, pose-preserving crop jitter, overlay and screenshot; preserve identity grouping. |
| Validation      | Macro across datasets/manipulations, demographic/quality slices and face-detection failure rate.           |

## Training recipe C - independent frequency branch

Use a compact CNN/ConvNeXt-tiny-style backbone over fixed SRM/high-pass residual channels or DCT statistics. Train with the same leakage-safe groups. Its promotion metric is not standalone accuracy; it must reduce correlated errors and improve selective risk when combined by an abstention policy.

## Reproducibility package

- Container digest, CUDA/cuDNN/PyTorch/Transformers versions and hardware.
- Dataset manifest hashes, license inventory and exact split membership.
- Config, seed, optimizer/scheduler state, checkpoints and code commit.
- Model card, intended use, limitations, prohibited uses and rollback predecessor.
- SBOM and malicious-model scan results; prefer immutable Safetensors/ONNX.

## 15. Benchmark, robustness and calibration package

### Required metrics

| Family           | Metrics                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Ranking          | AUROC, AUPRC, generator/manipulation macro AP.                                                                              |
| Operating points | Precision, recall, FPR, FNR, specificity and confusion matrix at every proposed threshold.                                  |
| Calibration      | Brier score, NLL, ECE, reliability curves and confidence intervals.                                                         |
| Abstention       | Coverage vs selective risk; error rate among accepted results.                                                              |
| Robustness       | Delta under JPEG/transcode, resize/crop, screenshot, blur/noise, overlays and social-platform transforms.                   |
| Fairness/slices  | Performance by source, camera, face size, pose, lighting, skin-tone/demographic slices where lawful and ethically governed. |
| Operations       | P50/P95/P99 latency, throughput, memory, provider errors, cost/job and fallback/abstention rates.                           |

### Promotion gates

- Unknown-label and provider-schema fixtures pass.
- No required slice falls below its declared floor.
- False-positive budget is met on consented production-like real images.
- Robustness delta remains within declared tolerance.
- Calibration and selective-risk targets are met with confidence intervals.
- Latency, queue and memory load tests pass at expected peak plus safety margin.
- Candidate beats or complements the production version and has an instant rollback target.

## 16. Exact implementation roadmap

Each phase is blocked until its exit gates are green

| Phase         | Deliverables                                                                               | Exit gate                                           |
|---------------|--------------------------------------------------------------------------------------------|-----------------------------------------------------|
| D0 - Truth    | Freeze tasks, current Pixel/Prism repos/commits/labels/licenses; shared schemas.           | Unknown contract fields fail before inference.      |
| D1 - Safety   | Restore DB migrations, behavioral tests, bounded media validation and capability registry. | Bomb/malformed corpus rejected before provider.     |
| D2 - Registry | Authoritative registry repository, calibration/benchmark tables, deterministic rollout.    | Executed and recorded model revision are identical. |
| D3 - Pipeline | Deterministic full-frame/face preprocessing, derived artifacts, quality evidence.          | Golden output hashes reproduce in CI.               |
| D4 - Models   | Strict adapters, candidate reproduction, optional independent secondary and abstention.    | All provider schemas and failure states tested.     |

| Phase          | Deliverables                                                                    | Exit gate                                                              |
|----------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------|
| D5 - Benchmark | Frozen evaluation, robustness, calibration, thresholds and model cards.         | Promotion report approved; otherwise remain shadow.                    |
| D6 - Integrate | One core under web, v1 and Gateway; evidence-first UI and compatibility window. | Same artifact/version yields same canonical evidence across endpoints. |
| D7 - Operate   | Async upload/jobs, SLOs, dashboards, drift, feedback, canary and rollback.      | Failure injection/load/rollback drills pass.                           |

## First engineering tranche

| Ticket                | Files/modules                                    | Acceptance                                                              |
|-----------------------|--------------------------------------------------|-------------------------------------------------------------------------|
| DFK-001 Contracts     | lib/contracts/*, runtime validators, fixtures    | Artifact/Evidence/Model/Version schemas reject unknown versions/fields. |
| DFK-002 Migrations    | supabase/migrations/* or governed migration root | Clean bootstrap, upgrade and restore in CI.                             |
| DFK-003 Registry      | lib/model-registry/*, admin repository           | Exact revision resolves before inference; main is prohibited.           |
| DFK-004 Label safety  | lib/deepfake/normalizer.js                       | LABEL_1/unknown/NaN/duplicates produce UNSUPPORTED_MODEL_OUTPUT.        |
| DFK-005 Media safety  | lib/media/*, worker validation                   | Pixels/frames/decode budgets and malformed fixtures pass.               |
| DFK-006 Compatibility | detection-service wrapper                        | Legacy consumers can project evidence without becoming internal truth.  |

# 17. Test architecture

## Test layers

| Layer                | Required cases                                                                                                   |
|----------------------|------------------------------------------------------------------------------------------------------------------|
| Unit                 | Registry resolution, label mapping, score validation, calibration transform, reason codes and state transitions. |
| Contract             | Known/unknown provider schemas, all Evidence states, API schema versions and compatibility projections.          |
| Media security       | Magic mismatch, truncation, pixel bomb, animation, huge metadata, odd channels and decode timeout.               |
| Golden preprocessing | Orientation, alpha, colorspace, resize, face crops, multi-face relationships and output SHA-256.                 |
| Integration          | Object storage -> queue -> worker -> provider fixture -> immutable evidence -> status API.                       |
| Failure injection    | Provider 429/5xx/timeout/schema change, registry outage, lease loss, cancellation and DB retry.                  |
| Benchmark            | Frozen manifests, metrics, calibration, slice/robustness deltas and release report.                              |
| E2E                  | Web and developer API render UNCERTAIN/UNSUPPORTED/FAILED without low-risk substitution.                         |

## CI lanes

- Every commit: syntax/lint, unit, contract, security fixtures and small golden corpus.
- Pull request: integration tests with local provider fixtures and clean database migration.
- Scheduled/GPU: robustness suite, candidate benchmark and drift report.
- Release: full benchmark delta, supply-chain scan, load/failure drill and rollback rehearsal.

# 18. Deployment and horizontal scaling

## Recommended production topology

Client -> authenticated API -> signed private object upload -> immutable artifact registration -> durable media queue -> validation/preprocessing worker -> per-model inference pools -> immutable evidence -> polling/webhook -> Gateway decision later.

## Service responsibilities

| Component           | Responsibility                                                    | Scaling signal                                 |
|---------------------|-------------------------------------------------------------------|------------------------------------------------|
| API/Vercel          | Auth, quotas, capabilities, upload registration, job/status APIs. | Request rate; no heavy decode/inference.       |
| Object storage      | Private encrypted artifacts and short retention.                  | Storage operations and retention backlog.      |
| Media CPU workers   | Hash, bounded decode, quality and deterministic preprocessing.    | Queue depth, CPU and memory.                   |
| Face detector pool  | YuNet/approved detector and derived artifact creation.            | Face-task queue and CPU latency.               |
| GPU inference pools | One pool per compatible model/runtime; batched where validated.   | Queue age, GPU utilization and tail latency.   |
| Evidence store      | Immutable registry/model runs/evidence and audit references.      | Write latency, orphan checks and index health. |

## Backpressure and reliability

- Tenant/global quotas and maximum in-flight jobs.
- Separate queues or priorities for preprocessing and expensive model execution.
- Per-provider/model semaphore, circuit breaker and bounded retry budget.
- Lease heartbeat, idempotency and cancellation at stage boundaries.
- Preliminary status remains HOLD/PENDING; missing model evidence never becomes safe.
- Autoscale on queue age/depth and measured service time; cap scale to provider/database capacity.

## SLOs to establish through load testing

- API registration availability and latency.
- P95 queue age and end-to-end job latency by model/task.
- Maximum provider error and timeout rate.
- Cancellation and retention completion latency.
- Evidence persistence integrity and orphan rate.

# 19. Observability, drift and feedback

## Metrics

| Family           | Examples                                                                                                 |
|------------------|----------------------------------------------------------------------------------------------------------|
| Reliability      | accepted/completed/failed/unsupported/uncertain, retries, queue age, cancellation and worker lease loss. |
| Providers/models | latency, 429/5xx/schema rejection, model revision distribution, circuit state and batch size.            |
| Media quality    | resolution, face detection success, blur/compression buckets and quality abstention.                     |
| Scores           | raw/calibrated distributions by model, preprocessing and quality slice; never raw images.                |
| Decisions later  | Gateway action distribution by policy/correlation/model versions.                                        |
| Feedback         | analyst labels, appeals, confirmed FP/FN, time-to-review and feedback coverage.                          |
| Integrity        | orphan evidence, revision mismatch, missing hashes, retention failures and migration drift.              |

## Drift rules

- Alert on provider output schema or label-set changes immediately.
- Track PSI/KS or declared distribution checks on quality, embedding and score features.

- Separate population drift from model regression and upstream preprocessing changes.
- Use delayed human/verified feedback to estimate production error; never treat model agreement as truth.
- Trigger shadow re-evaluation before retraining; data drift alone does not authorize automatic model updates.

## 20. Security, privacy, licensing and release governance

### Security controls

- Run image decode and third-party model loading in isolated, least-privilege workers.
- Use private storage, generated paths, short retention and verified deletion receipts.
- Never expose service credentials, provider model paths, signed URLs or raw content in logs.
- Scan model artifacts; prefer Safetensors/ONNX; maintain SBOM and pinned dependency lockfiles.
- Separate model build/training credentials from production inference identity.
- Rate-limit upload registration, status polling and API-key usage by tenant.
- Require explicit user authority to process faces; document biometric/privacy considerations.

### Licensing gate

A permissive model-code license does not automatically grant commercial rights to training data or pretrained weights. The registry must store model, code, dataset and upstream-weight licenses separately. FaceForensics++, DF40 and Community Forensics evaluation resources contain non-commercial/research restrictions. Obtain permission or build a consented/licensed commercial corpus before training production weights.

### Definition of done

- Every output can be reproduced from artifact, preprocessing, model, calibration and benchmark versions.
- No missing provider, parser failure, unknown label or disagreement becomes safe evidence.
- Every promoted model has a signed benchmark delta and rollback predecessor.
- UI and exports explain uncertainty and scope without an unexplained confidence percentage.
- Clean migration, security, resilience, load and rollback gates pass in CI/release rehearsal.

## 21. Interactive operator worksheet

Fill these fields before DFK-003 is implemented. The exact currently deployed model identifiers are intentionally not present in the repository.

### Current Pixel deployment

Hugging Face repository

Exact commit SHA

Scientific task

Raw labels / indices

Preprocessor / input

License approval

Current Prism deployment

Hugging Face repository

Exact commit SHA

Scientific task

Raw labels / indices

Preprocessor / input

License approval

Target operating context

Primary customers/use

False-positive budget

False-negative budget

Peak scans / minute

Maximum job latency

Retention requirement

22. Interactive implementation and release checklist

Truth and contracts

- ☐ Pixel exact repository, commit, task, label map and license recorded
- ☐ Prism exact repository, commit, task, label map and license recorded

- ☐ Artifact/Evidence/Model/Version schemas and runtime validators merged
- ☐ Clean database bootstrap, upgrade and restore pass
- ☐ Registry selects exact revision before preprocessing/inference
- ☐ Unknown/duplicate/non-finite provider output fails closed
- ☐ Dimension, pixel, frame, metadata and decode budgets enforced
- ☐ Preprocessing golden hashes reproduce in CI
- ☐ All qualified faces become related child artifacts
- ☐ Quality evidence and sufficiency rules implemented
- ☐ OOD claim is benchmarked or omitted
- ☐ Provider adapters preserve attempts, errors and exact versions
- ☐ Second model is independent evidence, not silent fallback
- ☐ LIKELY\_REAL/LIKELY\_SYNTHETIC/UNCERTAIN/UNSUPPORTED/FAILED implemented
- ☐ Frozen held-out benchmark and robustness report approved
- ☐ Calibration transform and thresholds approved
- ☐ UI/API display failure and uncertainty without low-risk substitution
- ☐ Signed upload, queue, backpressure and cancellation load-tested
- ☐ Provider/model/quality/drift dashboards and alerts live
- ☐ Shadow, deterministic canary and instant rollback rehearsed

### Final implementation starting point

Begin with DFK-001 through DFK-005: freeze Pixel/Prism semantics, restore migrations, introduce authoritative schemas/registry, remove heuristic labels and add bounded media validation. Do not implement training, calibration or a second detector before these correctness foundations pass.

END OF HANDBOOK
